

# Oxidation and Stabilisation of Polyethylene

Norman Billingham

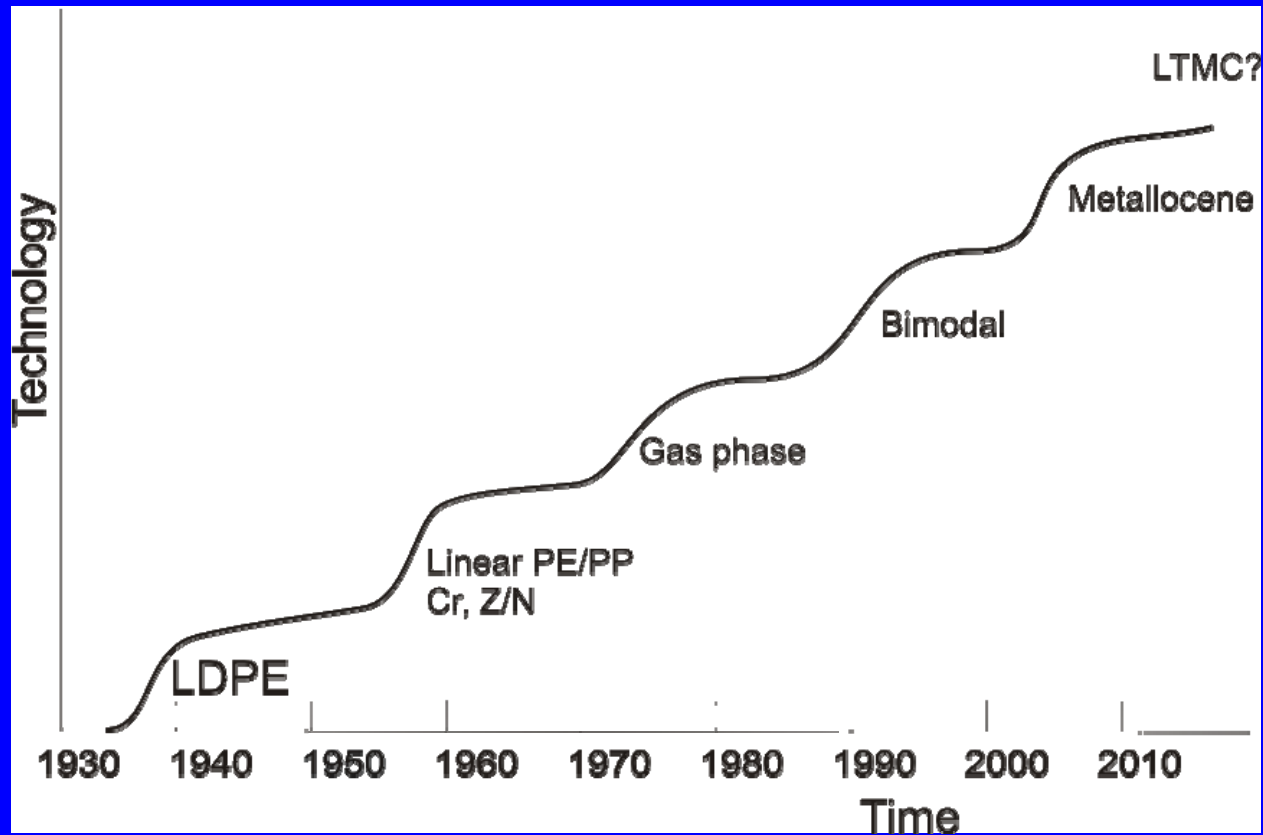

Department of Chemistry and Biochemistry,  
University of Sussex, Brighton, UK

# Polyethylene

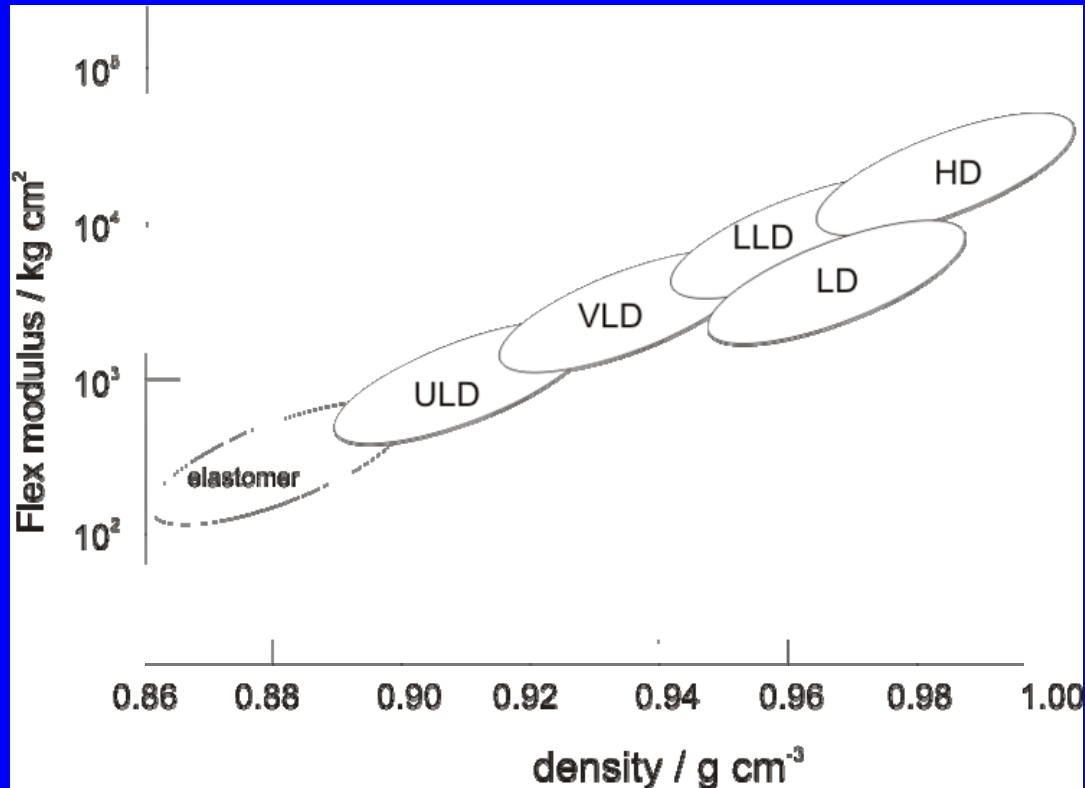

- The simplest polymer?
- Or the most complex?

# Polyolefin technology

# Polyethylene properties

# Properties of commercial PE's

Property	LDPE	HDPE	UHMWPE
Molecular weight	50,000 – 200,000	50,000 – 200,000	>2,000,000
Crystallinity /%	40	60	50-60
Density /gcm <sup>-3</sup>	0.91 – 0.93	0.94 – 0.97	0.93 – 0.95
Elastic modulus/MPa	100-500	400-1500	1000-2000
Elongation to break /%	50-800	40-1000	>300

# Crystallinity in polyethylene

- X-ray diffraction shows mixture of crystals and amorphous material

# Toughness in semi-crystalline polymers

- Crystallites act as “cross-links” and “fillers”
- Increase stiffness and toughness
- Polymer responds to load by chains pulling through crystals
- Critically dependent on “tie molecules”

The perfect nanocomposites?

# Sensitivity to degradation

- Since the properties of polymers, and of UHMWPE in particular derive from the long molecular chains, anything which breaks those chains can have a very profound effect on properties

n = 40,000

n = 20,000

Percentage of C atoms reacted = 0.003

# Formation of free-radicals

Energy from:

- Reaction of impurities in the polymer –peroxides
- Mechanical breaking of chains
- **Irradiation** –high-energy ( $\gamma$ , e-beam etc)

# Radicals from irradiation

# Reaction with oxygen

- Oxygen is always present in a polymer exposed to air
- Solubility is *ca* 1 mmol kg<sup>-1</sup> in the amorphous polymer and zero in the crystalline
- Reacts instantaneously with carbon radicals on encounter

# Reaction with oxygen II

- Peroxyl radicals are relatively stable but abstract hydrogen to make new C-centred radicals

- Overall we have a *chain reaction*

# The oxidation cycle

# Decomposition of hydroperoxides

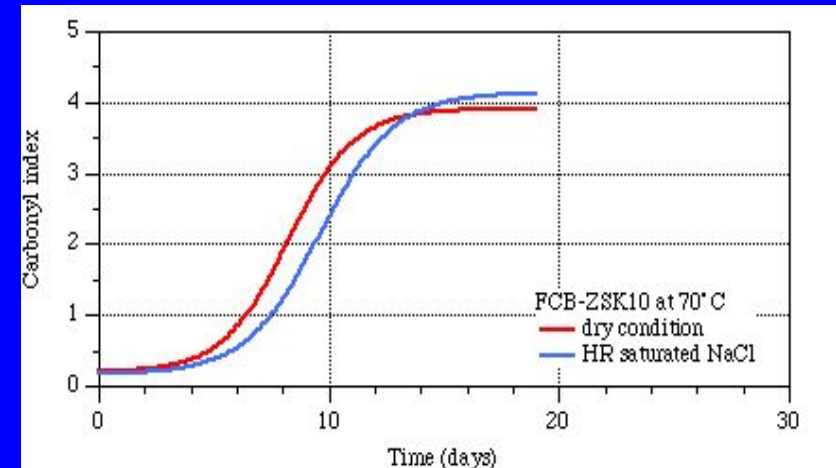

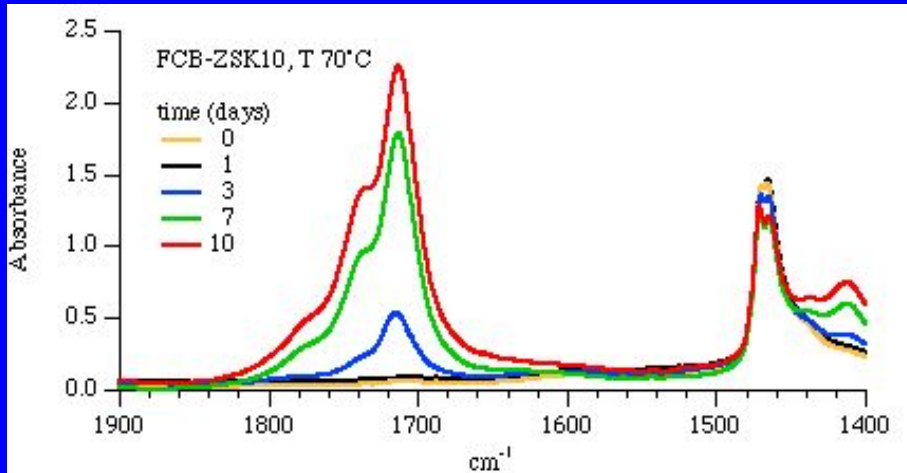

AUTOACCELERATION

# Chain scission reactions of alkoxy radicals

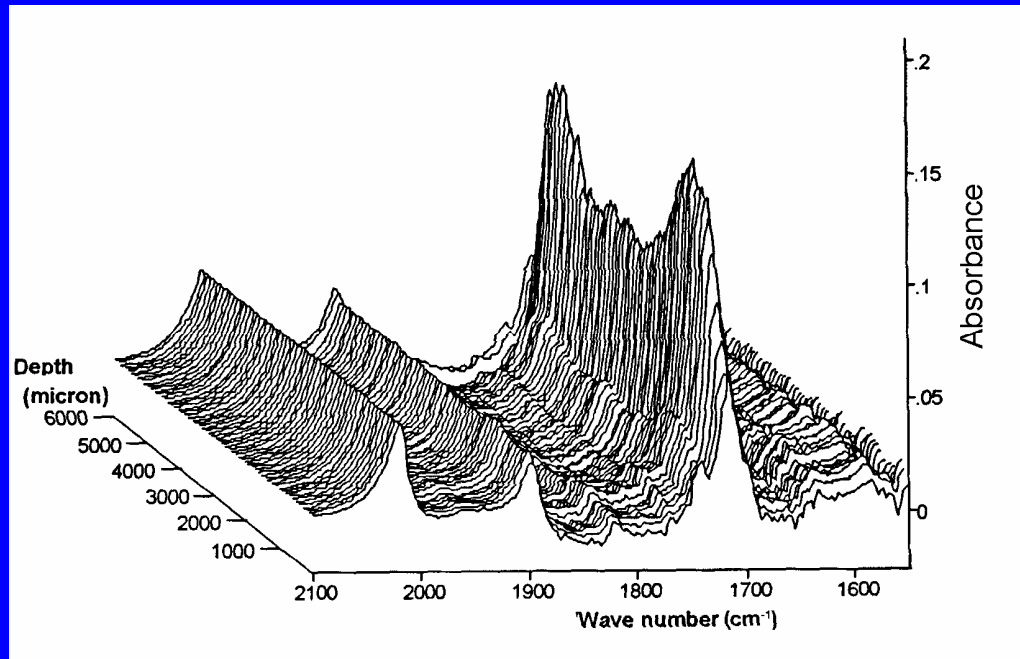

# Infra-red analysis of oxidation

- Development of bands in region 1700 – 1750 cm<sup>-1</sup> is characteristic of carbonyl-containing products of oxidation (ketones, acids and esters).

# Diffusion limited oxidation

Oxygen diffusion controls distribution of oxidation products through thick sections

# Effects of oxidation

- Oxygen incorporation increases density and hydrophilicity
- Chain scission allows recrystallisation – “chemicrystallisation”
- Increased density and crystallinity leads to surface cracking
- Polymer changes from tough to brittle

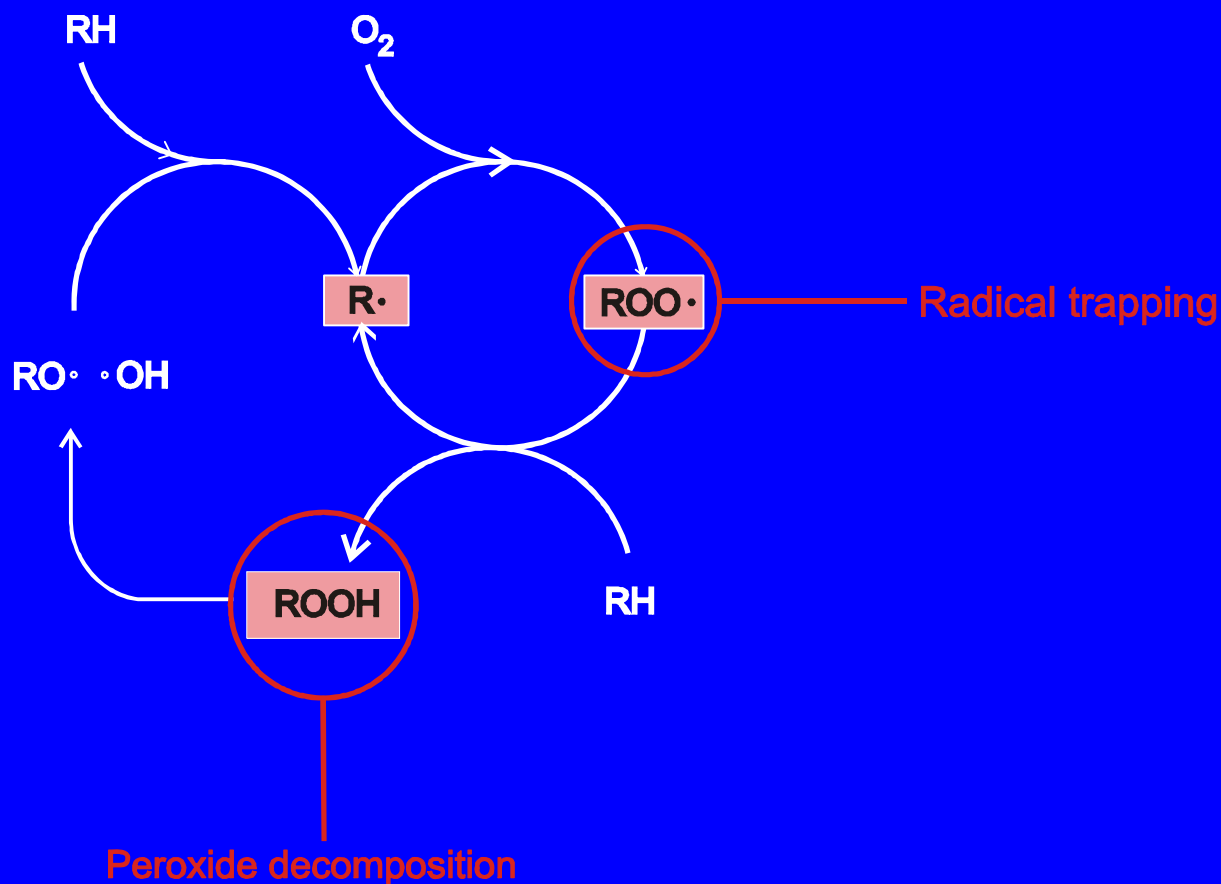

# Mechanical Properties

- Increased density and crystallinity leads to surface cracking
- Cleavage of tie molecules stops load transfer via crystals
- Overall – **loss of toughness**

Note that a polymer whose MW is reduced by degradation can be brittle even though a normal sample of same MW is tough

# Potential routes for stabilisation

# Simple phenolic antioxidant - BHT

- Able to trap peroxy radical
- Producing new radical too stable to reinitiate

# Requirements of an antioxidant

In addition to chemical reactivity an antioxidant must have:

- Thermal stability to survive processing
- Good solubility in hydrocarbon polymer
- Low volatility
- Low extractability into contacting liquids
- Low toxicity, especially in food contact

# Reaction products of phenolics

# Antioxidant synergism *in-vivo*

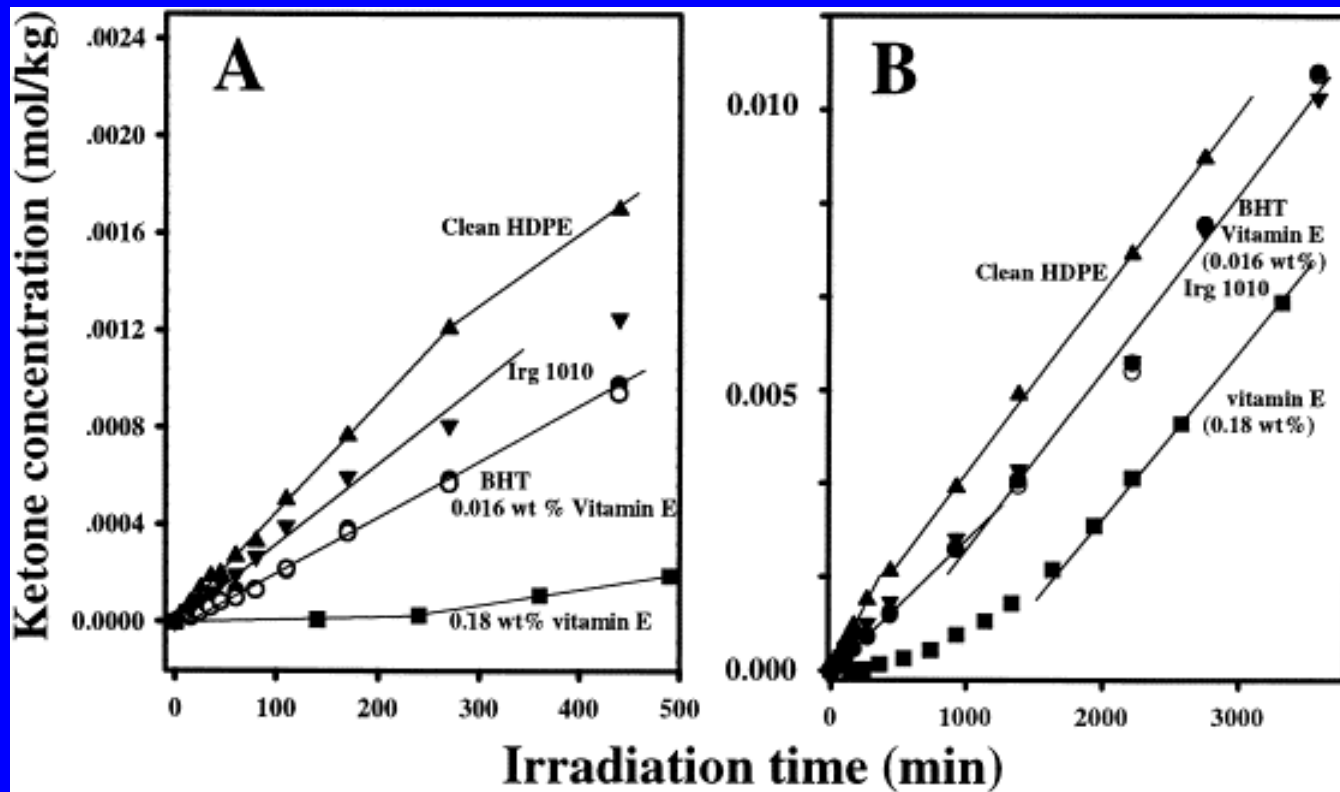

# Oxidation inhibition in hydrocarbons at 190°C

Breese, K D, Lamethe, JF, and DeArmitt, C, *Polym. Deg. Stab.*, 70, 89, 2000

# Stabilising effect of Vitamin E

Gamma induced oxidation of HDPE

# Oxidation products of tocopherol

# Conclusions

- Polyethylene gets its mechanical properties from the combination of long chain length and semi-crystalline morphology
- Chemically insignificant amounts of oxidative degradation affect mechanical properties profoundly by cleaving the important “tie molecules”
- Oxidative degradation is easily initiated by  $\gamma$  or e-beam radiation

# Conclusions II

- Detailed mechanisms may depend on local solid-state mobility – especially UHMWPE
- Antioxidants are added to essentially all PE products to inhibit oxidation during processing and end use
- Most commercial antioxidants would be excluded from use in medical devices due to potential migration and toxicity
- Vitamin E has potential for medical applications
